Physical activity and health promotion strategies among physiotherapists in Rwanda

*Frantz JM, Ngambare R

Department of Physiotherapy, University of the Western Cape, Bellville

Abstract
Background: Physical inactivity has become a global health concern and is among the 10 leading causes of death and disability. Physiotherapists are in a position to combat inactivity and effectively promote physical activity to their clients.

Objectives: To establish the relationship between physical activity levels of physiotherapists and their physical activity promotion strategies.

Methods: A sequential mixed method design was used by means of a self-administered questionnaire (n=92) and a focus group discussion comprising of 10 purposively selected physiotherapists. Descriptive statistics were employed to summarize demographic information. Inferential statistics was used to test the associations between different categorical variables (p<0.05). Tape recorded interviews were transcribed. Thematic analysis was then done.

Results: The findings revealed that 64% of the participants were physically active both within the work and recreation domains and 65% of the participants had good physical activity promoting practices. Discussing physical activity and giving out information regarding physical activity were most common methods used in promotion of physical activity. Policies on physical activity, cultural influence, and nature of work, time management as well as the environment were the barriers highlighted.

Conclusion: Although physiotherapists experience barriers to promoting physical activity, they have good physical activity promoting practices.

Key words: physical inactivity, chronic diseases of lifestyle, health promotion strategies, physiotherapy, Rwanda African Health Sciences 2013; 13(1): 17 - 23

Introduction
The World Health Organization has described chronic diseases of lifestyle as the leading cause of mortality in the world, representing 60% of all deaths1. The burden of mortality, morbidity and disability attributable to chronic diseases is currently greatest and is continually growing in the developing countries. It was estimated that by 2020, chronic diseases associated with diet and lifestyle in Sub-Saharan Africa will constitute almost 50% of the burden of disease23. Literature has highlighted that lack of physical activity, unhealthy diet, tobacco and alcohol use contribute in a large part to chronic diseases of lifestyle4. Physical inactivity has been identified as a serious global public health problem which is associated with numerous preventable diseases and has been classified as the fourth leading risk factor for global mortality5. The World Health Organization estimates that globally the prevalence of physical inactivity among adults is 17%, ranging from 11% to 24% across different regions of the world1.

In order to combat this health concern linked to physical inactivity there is a need for health promotion interventions that focus on single factors such as physical inactivity. It has been argued that primary healthcare professionals such as physiotherapists are ideally placed to promote physical activity within local communities to combat the impact of chronic diseases of lifestyle. “Many health professionals including physiotherapists take health promotion as an integral part of their role” as health promotion and health education are currently one of the core competencies expected from the physiotherapy profession6. It is further indicated that physiotherapists should prioritize and organize their efforts based on their skills and knowledge of physical activity and guided by community preventive evidence based recommendations for promotion of physical activity to advocate for the inclusion of physical activity policies in various settings7. Within the primary health

care setting, health professionals are considered an important part of a wider public health drive to encourage more people to become physically active. If physiotherapists should advocate and address health promoting physical activity then they could promote health holistically.

The conceptualization of health promotion in physiotherapy is different from other fields of health promotion which emphasize empowerment as the central concept of health promotion but instead health education is the most emphasized health promotion strategy in physiotherapy. Researchers have indicated that “health education and health promotion activities are a fundamental requirement for all health professionals. These two paradigms are closely related but are not inter-dependent” [8]. Worldwide, the World Health Organization is advocating for physical activity as a preventive measure to chronic diseases of lifestyle. While a growing body of literature supports the effectiveness of physical activity interventions delivered in the primary care setting, few studies have evaluated efforts concerning the use of physical activity as a health promoting strategy by physiotherapists. The aim of the study was to establish the physical activity levels of physiotherapists in Rwanda and their physical activity health promotion practices.

Methods
The study employed a sequential mixed method design and was conducted in referral and district hospitals of Rwanda. The quantitative method was a descriptive cross section survey and the qualitative component incorporated a focus group discussion. In Rwanda there are 160 registered physiotherapists of whom 142 registered physiotherapists worked in public and private hospitals, clinics and institutions of higher learning. For the current study physiotherapists working in the referral and district hospitals (n=104) were targeted for the quantitative aspect of the study. In addition, ten physiotherapists from the study sample were purposively selected to participate in the focus group discussions based on the outcomes of the Physical Activity Exit Interview (PAEI) questionnaire completed by participants in the quantitative component.

Data from the physiotherapists were collected by means of self-administered questionnaires which consisted of 3 sections. The first section requested for demographic information and information on physical activity based on the reliable and valid World Health Organization Steps framework instrument for non-communicable diseases risk factors [10,11]. The WHO STEPS surveillance instrument has been used in various African countries [12,13]. Another section of the questionnaire was the valid and reliable Physical Activity Exit Interview (PAEI) which measured the content of physical activity promoting practices by physiotherapists [14]. In the focus group discussion an interview guide with probes for discussions was developed based on the aim of the study and literature.

Ethical clearance was obtained from the ethics committee at UWC (10/8/20) and permission was obtained from the Ministry of Health, the Rwanda national ethical committee, and the directors of the hospitals at which the study was conducted. Written informed consent was obtained from all participants and they were informed that participation was voluntary. Permission was also obtained from the participants in the focus group discussion to use a tape recorder to capture audio data during the focus groups discussion and a confidentially form was signed by all participants.

Data for the quantitative study was analysed using the Statistical Package for Social Science (SPSS) version 18.0. Descriptive statistics was employed to summarize the demographic data and a continuous indicator of Metabolic Equivalent Task (MET) was used to estimate the mean physical activity levels of the sample, the total time spent in physical activity in a typical week, the number of days as well as the intensity of physical activity. Inferential statistics using the chi-square was employed to compare association between physical activity levels and other variables like physical activity promoting strategies (p< 0.05).

For the qualitative data, analysis included, transcribing interviews, typing field notes, sorting and arranging data, making sense and overall meaning of information and coding information into categories. The narrative data was subjected to the process of interpretation and analysis.

Results
All physiotherapists practicing in referral and district hospital were invited to participate in the study yielding a total of 104 physiotherapists. Of the 104 questionnaires distributed, a total of 92 physiotherapists voluntarily participated in the study giving a response rate of 88.5%. Among the participants, males accounted for 70% (n= 64) and females 30% (n=28). The participants’ age ranged
from 26-60 years, with a mean age of 32.49 years (SD = 6.56). Participants had work experience of ranging from between 1 year to 34 years, with a mean working experience of 1.62 years (SD = 1.03). Most of the participants’ highest education level was a diploma (70%), followed by a BSc degree (21%) and a Masters degree (9%).

Physical activity levels in relation to physical activity domains
According to reported physical activity levels, 28% were classified as sedentary, 33% moderately active and 39% vigorously active. Participants’ physical activity levels were assessed with regard to the different physical activity domains such as: work, transport and recreational activities. The highest mean MET-minutes/week (2685.9) was recorded at work, followed by the recreational physical activity domain (table 1).

Physical activity promoting practices
Physical activity promoting practices were analyzed using the Physical Activity Exit Interview Questionnaire and the study found that 65% had high physical activity promoting practices, 32% had moderate physical activity promoting practices and 3% had poor physical activity promoting practices. No statistically significant association was found between physical activity levels and physical activity promoting practices (p>0.05). Participants below the age of 35 years had higher physical activity promoting practices (51%) than any other age group and males (46%) had high physical activity promoting practices compared to the females (20%). The most common form of health promotion strategies used by physiotherapists included discussing physical activity participation with their clients (98%), rather than the use of written material (9%).

Barriers to physical activity health promoting practices
Participants in the focus group discussion consisted of 5 participants who had good physical activity health promoting strategies and 5 who had poor physical activity health promoting strategies. In the focus group discussions with the participants, four themes emerged as the barriers to promoting physical activity among clients with six categories and eleven subcategories. The themes, categories and subcategories are presented in Table 2 and supported with relevant quotations.

**Discussion**

Physical activity has been globally recognized to have the solution and prevention of increasing chronic diseases of lifestyle. Increase in physical inactivity is evidence that the world population is engaging less in physical activity. Health professionals, especially physiotherapists are in a better position to promote physical activity among their clients. Although physiotherapists may have the knowledge, the promotion of physical activity as a health promotion strategy is influenced by various factors such as personal practices, the cultural beliefs of the population factors and policy.

In the current study, physiotherapists in Rwanda were equally represented in all categories of physical activity level participation, with them being most active whilst at work. Compared to other health professionals in South Africa, research found that most nurses working in public hospitals were considered to be sedentary. The difference between physiotherapists and the other sample population may be due to their knowledge of physical activity acquired during their training when still in school compared to other populations. Physiotherapists are perceived as experts in the promotion of physical activity. It is in this regard that their clients/patients and other health professionals respect their advice concerning health matters. This puts physiotherapists in the best position to advocate and influence their clients’ participation in physical activity. In the current study discussing physical activity and the use of written materials on physical activity were the strategies used in promoting physical activity to clients/patients. These strategies are similar to those commonly used in New South Wales, Australia where it was reported that physiotherapists used some of these strategies to promote physical activity. Other health professions like doctors, did not use written materials or give written exercise plans to their patients. It was also revealed that it was easier for dieticians to discuss physical activity than giving written material since it’s time consuming and costly.

What is important from the current study is the emphasis on the cultural influence on physical activity participation as indicated by the following quote “The Rwandan Culture plays a big role in influencing physical activity. It prevents some groups of people from participating in physical activity for example women were not allowed to participate in physical activity.” This lends us to understand the role of cultural competence as a core skill among health professionals. However a study
conducted by Murrock and Madigan helps us to focus on culture in a way that promotes physical activity. In most cultures traditional dances and positive lifestyle activities are encouraged thus it can be used to promote physical activity and researchers are encouraged to explore the positive aspects of culture on physical activity. In addition, to improve cultural beliefs as mentioned by the participants in the current study, research highlighted that for national policies and plans on physical activity to be implemented and be successful, they should be socially inclusive and participatory. Therefore cultural ties and influence should be considered.

Finally, if health promotion strategies are to be plausible, it should be guided by policy as is the case in Rwanda. However, challenges exist and if these challenges are not addressed effectively the policy will not serve its purpose. It has been highlighted that for national policy to be implemented effectively, all stakeholders should comply and develop institutional policies that work hand in hand with the national policy and have effective collaboration in all physical activity programs. Therefore responsibility should be defined at every level so that activities should not overlap.

Conclusion
Based on the findings of the current study, it is evident that physically active physiotherapists are well positioned to incorporate health promotion strategies that can encourage patients to participate in physical activity. However, the successful implementation of these health promotion strategies related to physical activity is still influenced by barriers such as government policy, cultural influences, environmental influences and time constraints experienced by the practitioner.

Implications for practice
It is thus important for physiotherapists and other health professionals to be empowered about intervention strategies within the limited resources we are faced with and governments should streamline the policy on physical activity for better promotion of physical activity.
