South Africa is experiencing an increase in the prevalence of non-communicable diseases (NCDs), which imposes a heavy burden on healthcare services. The South African government has made great strides towards management and control of NCDs, including the development of management guidelines, health-promotion and prevention policies intended to assist healthcare workers, facilities and communities in NCD care. However, it appears that the facility-based component of NCD management and control efforts has received more attention than the community-level components.

The national strategic plan for NCDs highlights the importance of community-level interventions in chronic NCD care. Thus there is a need for community-based strategies for NCD prevention, control and management to complement facility-based health services.

This chapter explores the advancement of the NCD agenda in South Africa through an emphasis on community-level prevention and management. It describes interventions that used community actors such as community health workers in NCD care. The chapter discusses some of the challenges of these interventions, and ends with possible suggestions for South Africa.

The national strategic plan for non-communicable diseases emphasises the need for community-based strategies for prevention, control and management to complement facility-based health services.
Introduction

Non-communicable diseases (NCDs) such as cardiovascular diseases (CVDs), cancers, chronic respiratory disease and diabetes are the leading cause of mortality and disability globally. Eighty per cent of NCD deaths reportedly occur in low- and middle-income countries (including South Africa), affecting disproportionately more individuals younger than 60 years than in high-income countries. In South Africa, the probability of dying between 30 and 70 years of age from CVDs, cancers, chronic respiratory disease or diabetes is about 27%. These death and disease burdens are largely driven by preventable risk factors.

The risk factors for NCDs are well known and include tobacco use, harmful consumption of alcohol, unhealthy diet, obesity and physical inactivity. Dietary factors and physical inactivity remain two of the most significant risk factors for NCDs in South Africa, with the former influenced by the food environment. Many of these risk factors can be reduced through existing preventive interventions, as well as through early detection of individuals at risk and those who have undiagnosed conditions. Prevention and early detection measures are therefore crucial for the control and management of NCDs, and failure to implement such interventions can be costly.

Globally, there have been efforts to reduce the burden associated with NCDs. This is evident in the formulation of NCD-related policies and the inclusion of a specific Sustainable Development Goal (SDG) targeted at reducing premature NCD mortality by one-third by 2030. Furthermore, the World Health Organization (WHO) Global Action Plan for the Prevention and Control of NCDs 2013–2020 recommends that each country commit to setting targets and strategies to reduce NCD morbidity and mortality. The development of NCD-related policies and the use of population-based approaches for tackling NCDs highlight the importance of dealing with these conditions.

However, policy development alone will not translate into NCD control. Policies must be translated into action at various levels of society, including community level. An improved response to NCDs at community level calls for new thinking that engages available resources to deliver care, especially in low-resource settings.

Current NCD policy and implementation

The South African National Department of Health (NDoH) has taken various steps to improve NCD management, including the establishment of units specifically responsible for NCD prevention and control. Also, NCD control-related policies have been designed and implemented over the years. In a landmark development, the 2011 summit on NCDs set the stage for a new multisectoral NCD response, which ended with stakeholders agreeing to new national NCD management and control targets contained in the South African NCD Declaration. The Declaration paved the way for the “Strategic plan for the prevention and control of non-communicable diseases 2013–17”, which detailed arrangements for NCD prevention and control in South Africa. Notably, the strategic plan focuses on preventing NCDs and promoting health; strengthening health systems for NCDs; and monitoring progress.

Preventing NCDs and promoting health subsequently became a central focus of policies developed for NCD management. One such policy is the National Health Promotion Strategy and Policy 2015–2019, which provides a framework for general disease prevention in South Africa. This aligns closely with the 2011 Declaration on NCDs and also conforms to the overall WHO Global Action Plan for the Prevention and Control of NCDs. Other policies targeting NCD risk factors include the Liquor Act of 2003 and the Tobacco Product Control Act of 1993 (amended in 1999, 2007, 2008 and 2016), designed for alcohol and tobacco consumption control respectively. Policies and strategies are being designed that improve dietary intake and counter the overwhelming influence of ‘Big Food’ and its impact on NCDs. The Strategy to Prevent and Control Obesity 2015–2020 and the National Food and Nutrition Security Policy are some of the policies targeting the food environment and NCDs. As part of the strategy to reduce obesity by 10% by 2020, the South African Treasury plans to increase the price of sugar-sweetened beverages by means of a 20% fiscal tax.

The NDoH passed new Regulations on the Foodstuffs, Cosmetics and Disinfectants Act (54 of 1972) to reduce salt intake from processed food in the country, with implementation commencing in 2016. While empirical evidence shows reduction in tobacco consumption in South Africa after the introduction of tobacco control, the impact of other NCD control policies remains to be seen. This suggests a gap between plans and implementation.

In order to address apparent gaps between macro-level planning and micro-level implementation, the NDoH introduced the Primary Health Care (PHC) Re-engineering policy to facilitate integration of NCD prevention and control into general health management. The expectation is that health-facility teams working with Ward-based Outreach Teams (WBOTs), comprising nurses and community health workers (CHWs) are able to deliver integrated NCD services to individuals in their households and communities. Although the PHC Re-engineering Strategy has its challenges, notationally it provides a good platform for improved community-level prevention and management of NCDs. In designing this policy, health policymakers recognised the critical importance of community-level efforts in the fight against NCDs. The NDoH’s Ideal Clinic initiative and the Integrated Clinical Services Model (ICSM) offer opportunities for NCD management and integration between facility and community levels. However, there is a need for ‘consistency of purpose’ connecting the macro (policy) and the micro (community) environments of NCD prevention and control.

While NCD policies and strategies exist in South Africa, their impact in reducing the NCD burden in the country will depend on the capacity and readiness of the health system to implement and monitor proposed strategies successfully.

Health-system readiness

The WHO defines the role of health systems in the prevention and control of NCDs as including universal coverage; protecting people from the burden of ill-health associated with NCDs through people-centered PHC; making resources available for the care of people with NCDs; as well as preventing complications and reducing mortality. The health system is also expected to build the capacity of communities to take responsibility for their health through actions...
such as advocating for reduced exposure to modifiable NCD risk factors, and making healthy choices in their living and work environments. At the very minimum, the South African health system should be able to perform these functions in combating NCDs.

One of the main targets of the National Strategic Plan for NCDs is strengthening of national capacity and reorientation of the health system to address NCDs. The PHC Re-engineering Strategy stipulates the use of WBOTs, District Clinical Specialist Teams (DCSTs), and School Health Teams to provide screening and disease-detection services in schools and communities. Availability and readiness of these cadres of healthcare workers (HCWs) remain a challenge. Community-health systems for NCD prevention and control appear to lag behind facility systems. There is heavy reliance on facilities for NCD management. However, as discussed next, it is evident that the facility system is not adequately equipped to deal with the NCD challenge.

Availability and capacity of health providers in NCD management

Evidence suggests that between 1997 and 2006, little progress was made in improving the availability of HCWs in South Africa's public-health sector. However, improvements have been made more recently. Between 2004 and 2010, the overall number of workers in the public-health sector increased quite considerably, from 153,383 to 210,511, mainly in the nursing sector. However, this increase is not necessarily adequate to cater for the increasing burden of NCDs and other diseases. Most of the documented increase in the number of HCWs has been in the number of facility-based staff, with little or no mention of community care workers. The capacity of available HCWs to implement policies and strategies is equally important, but is not adequate at present.

Studies assessing the management of patients with diabetes and hypertension at PHC facilities have reported suboptimal management and poor compliance. In one study in Soweto, Brand and colleagues found that both hypertensive and diabetes patients were poorly managed and were not screened for CVD risk factors. Staff shortages, resulting in reduced time to counsel patients with NCDs and poor communication between patients and health workers, are some of the factors reported as barriers to management and control of NCDs globally.

There have been initiatives to improve the capacity of HCWs to deliver NCD care in South Africa. Nurses are the major care providers for NCD patients in PHC facilities in South Africa, and as such they have been trained in evidence-based management guidelines, known as ‘Primary Care 101’. An evaluation of the impact of the Primary Care 101 training found that diabetes and hypertension management skills improved among nurses, but the management of asthma and other chronic obstructive pulmonary diseases did not. This was attributed in part to the fact that diabetes and hypertension were common conditions in the studied population, which exposed the nurses to experiential learning. There is a need to explore the utilisation of other cadres of health workers, including CHWs, to manage NCDs.

One of the strategies recommended for circumventing these health system-related challenges is ‘task-shifting’, whereby a task normally performed by a physician is shifted to a health professional with a different or lower level of education and training, or to a specifically trained person who performs a limited task only, without having formal health education.

The PHC Re-engineering Strategy encourages the shift of disease-management tasks from physicians in health facilities to nurses and CHWs in communities and other primary care settings. Implementation of the PHC Re-engineering Strategy and other strategies (e.g. the Ideal Clinic initiative) has led to an increase in the number of PHC facilities with functional clinic committees and WBOTs, thus increasing access to community-based PHC services. There is a need to strengthen these strategies and enhance community capacity for NCD management.

Although the prevention of NCDs should be part of PHC services, these services are still weak in many places in South Africa. Patients still access health care at inappropriate levels, and community-based hospice and palliative care is mainly provided by non-governmental organisations (NGOs) and not by government.

Health financing

The importance of health financing for management and control of NCDs at community level cannot be overemphasised. South Africa included NCDs in the National Development Plan (NDP) and has a target of 28% reduction of incidence by 2030. Funding for NCDs forms less than 0.1% of the national health budget; it is not clear how much of this funding is dedicated to community NCD services. There is evidence of increasing budgetary allocation to PHC care. Table 1 shows the increased spending budget for services that provide PHC, with the highest annual growth observed in district management and community health clinics. Despite increasing budgetary allocations to PHC and community services, there is insufficient information on how much is dedicated to the community care system itself.

### Advocacy for community-level NCD management

The South African health system includes several policies and strategies for NCD management9,11,42 However, it is not very clear how the community system has been strengthened and leveraged in the fight for disease control. Examples of where the community system has been successful include management of HIV and AIDS and tuberculosis. To strengthen the case for improved community-level NCD prevention and management, we present a few examples of how community resources have been utilised to improve disease management. Central to these community resources are CHWs.

### Effectiveness of community-level NCD prevention and control interventions

Table 2 presents a summary of selected NCD interventions using community-based strategies, mainly utilising CHWs. Interventions described focus on NCDs such as hypertension, diabetes, cancer and CVDs.

<td>Ndou et al. (2013)46</td>
<td>To examine the outcomes of a pilot CHW programme to improve the management of hypertension and diabetes. Gauteng Province</td>
<td>CHWs provided social support and counselling to improve patient literacy and adherence, and to encourage appropriate visits to the PHC clinic. A monthly supply of medication was delivered to named patients.</td>
<td>The course focused primarily on home-based care and provided skills in adherence, counselling and health promotion, with a particular focus on chronic illnesses, including hypertension and diabetes. Training duration was 14 weeks.</td>
<td>Hypertension control improved with CHW home visits compared with usual clinic care. However, the inverse was found for diabetes control. When both conditions were considered, hypertension control was higher in the intervention group than with usual clinic care.</td>
</tr>
<tr>
<td>Gaziano et al. (2014)47</td>
<td>To determine whether training CHWs on hypertension in order to improve adherence to medications is a cost-effective intervention among community members in South Africa.</td>
<td>In this simulated intervention, six CHWs measured blood pressure using an automated blood-pressure cuff. Each CHW was given a list of hypertensive patients registered at a nearby clinic and it was estimated that she could make six home visits per day.</td>
<td>In this simulated intervention, six CHWs were trained to measure blood pressure using an automated blood-pressure cuff. Training was also given on the aetiology and prevention of hypertension and CVD. Training duration was two days.</td>
<td>The CHW intervention was found to be cost-effective and led to an incremental cost-effectiveness ratio of $320/ Disability-Adjusted Life Year averted.</td>
</tr>
<tr>
<td>Turn et al. (2013)48</td>
<td>To develop and pilot-test an intervention to address low cervical screening uptake as well as a potentially low breast-screening uptake. Tshwane</td>
<td>Community members were trained to become CHWs. However, one member was specifically trained to work in cancer prevention. The assessed outcomes for this study were: screening uptake; awareness; and value of the CHW. The study utilised a post-intervention design.</td>
<td>CHWs were trained and tasked to raise awareness of cervical and breast cancer and to motivate women to take up screening. Training was conducted over a period of three months.</td>
<td>Intervention showed that CHWs were valued but uptake of cervical screening and awareness remained low.</td>
</tr>
<tr>
<td>Gaziano et al. (2015)49</td>
<td>To investigate whether CHWs could do community-based screenings to predict CVD risk as effectively as physicians or nurses, with a simple, non-invasive risk-prediction indicator in low- and middle-income countries. South Africa, Bangladesh, Guatemala, Mexico</td>
<td>Observational study CHWs who successfully completed the training screened community residents to predict CVD risk. Trained to calculate an absolute CVD risk score with a previously validated simple, non-invasive screening indicator. Duration of the training was 1–2 weeks and included both practical and didactic components. No information on retraining.</td>
<td>Mean level of agreement between the CHW and health professional scores was 96.8% for the overall study and 97% for South Africa.</td>
<td></td>
</tr>
</tbody>
</table>

**Key findings and lessons learnt**

Key findings from the studies described in Table 2 include the following:

- CHWs are effective when used in the delivery of clinical outcomes for NCDs;
- there are differences in training strategies;
- community-based interventions differ according to the targeted outcome; and
- NCD interventions are suitable for resource-poor settings, which is the case in many areas in South Africa.

In addition, several lessons can be learnt from the research studies presented in Table 2. The studies show that the scope of CHW practice ranges from NCD prevention to control. The study by Gaziano and colleagues clearly demonstrates that CHWs have the ability to screen community members for CVD risk; furthermore, the accuracy of CHWs was found to be similar to that of professional health staff.49 However, despite CHWs’ ability in executing NCD-related tasks, their effectiveness in improving NCD-related health outcomes is not well documented. Evaluation of health outcomes will strengthen the case advocating for the use of CHWs at community level, especially in resource-limited settings and areas where there is a lack of nurses and doctors.

The breadth of work undertaken by CHWs was found to vary widely, based on intended health outcomes. Their tasks included measurement of height and weight, monitoring of blood pressure and blood-glucose level,35-37,39 as well as screening and health education.38 These tasks are usually performed in formal health facilities; as such, the studies provide evidence that CHWs have the ability to extend services beyond health facilities when trained appropriately.

Training of CHWs is crucial in capacity-building, with the cited studies showing varied training duration. In a country where the educational attainment of CHWs varies, duration of training is critical. Furthermore, duration of training can have an impact on follow-up training. It has been shown that follow-up training is necessary for retaining knowledge;50-52 this is even more the case for this cadre of workers who lack continuous education opportunities.

Despite the usefulness of these interventions, several issues should be borne in mind when considering them, especially in terms of
scale-up. High-performing CHW subsystems should be integrated into the PHC system, and there must be investment in supervision that extends into health facilities. As CHW models become more formalised and integrated into the formal healthcare system, training must be better structured. Apart from training, it is equally important to ensure that CHWs have the appropriate materials in order to fulfil their tasks.

In the interventions cited in Table 2, researchers had the necessary resources for the execution of tasks. Other studies have reported that in resource-poor settings, CHWs often lack the resources and supplies needed to perform their daily tasks, thus lack of supplies can hinder performance. In addition, the scope of practice for CHWs may have implications for the number of workers needed to deliver services to communities. Failure to increase the number of CHWs will mean that they either offer fewer services or reach fewer households. These are some of the elements that must be in place for CHW programmes to be successful and effective.

Potential gains

Gains in community-level NCD prevention and control, especially when CHWs are utilised, can be measured at three major levels, namely patient, care-provider and national-resource levels.

For the individual, gains include disease prevention due to health-promotion messages and services delivered early and closer to home in the community. There is also reduced transport and other associated costs for individuals already affected with NCDs if they receive services at home from a CHW.

For the care providers, gains include reduced facility visits with less overcrowding as fewer people develop NCDs and attendant complications.

For the country, gains include fewer resources spent on NCD management, with disease averted by health promotion and complications delayed or totally averted by early detection.

Based on the evidence presented in this chapter, we have formulated our recommendations focusing on three areas, namely the CHW programme, health information and financing.

These recommendations are formulated to improve the utilisation of CHWs in the prevention and control of NCDs at community level.

The CHW Programme

- Community and facility interaction: Successful interaction between the Ideal Clinic and the WBOT stream of PHC re-engineering is crucial. Community health workers are well positioned to be the fulcrum of a successful interaction. If properly co-ordinated, this can ensure smooth integration between community (promotive and preventive) and facility (curative and rehabilitative) NCD services.

- CHW training and retraining: There should be a standardised curriculum for NCDs. In addition, training should focus on core tasks, based on evidence, which will result in a more focused training programme. Retraining is crucial, thus dedicated trainers should be identified, as should appropriate intervals for retraining.

- Supportive supervision: Constant supervision that is non-judgmental can assist in improving the confidence of CHWs in executing their tasks. In addition, supervision has the potential to provide a non-threatening space that facilitates interactive learning.

- CHW scope of work: The CHW scope of work must be clearly defined, so that workers are able to provide a comprehensive service to communities. In resource-limited settings where CHWs are required to provide a plethora of services, defining their NCD-related tasks will ensure that they offer realistic service, without compromising on the quality of service.

Health information

As with HIV and AIDS, translating NCD policy into action will require a carefully designed monitoring system. Currently, indicators set for NCD monitoring appear inadequate and inappropriate for providing information for effective NCD control. Because of the greater emphasis on promotive and preventive health action, the South African health-information system should be improved to highlight progress in NCD prevention. Importantly, as most promotive and preventive health actions occur in the community, the health-information system should be strengthened for adequate information collection and reciprocal use at community level.

Capacity for useful and relevant data collection must be enhanced. Healthcare workers providing community-level NCD activities are a useful resource that should be capacitated to form part of the health-information system for NCD. Process, outcome and impact indicators for NCD monitoring and management are needed, and several of these will be crucial at community level.

Financing

There is a need to pursue alternative funding for CHWs. Donor agencies should be leveraged to finance community involvement in NCD management, as has been the case with other chronic conditions such as HIV and AIDS. Furthermore, there is a need to look at the cost-effectiveness of utilising CHWs in a setting such as South Africa, as a cost-effective approach will strengthen the importance of community-based interventions for NCDs.

Conclusion

Evidence shows that there are flaws in the management of NCDs in the formal healthcare system, suggesting the need to provide services that extend beyond health facilities to communities in order to advance the NCD agenda. Community-level prevention and control of NCDs in resource-limited settings is crucial for continuity of care. Community health workers have provided health care within communities for decades; therefore, they can potentially provide NCD care while also connecting individuals to the formal healthcare system. Numerous systems, such as funding, training and retraining, and supportive supervision, should be put in place to enable CHWs to provide adequate services. Furthermore, they require support from other parts of the formal healthcare system, especially at the primary level of care. A strong community-based focus and a functional formal healthcare system have the potential to avert the burden of NCDs.
