Abstract

This study aimed to identify psychosocial correlates of intimate partner violence (IPV) by using constructs derived from the self-determination theory (SDT) and gender-power scales. Cross-sectional data ($N = 238$) were collected from women in the Eastern Cape, South Africa, and were used to test a structural equation model (SEM). The majority (87%) of the participants reported having sexual partners in the past 3 months, and in terms of IPV victimization, 36% and 26% of women had ever experienced verbal and physical abuse, respectively. Bivariate correlations showed that autonomy and beliefs about gender equality (BGE) were strongly associated with IPV. This finding was also confirmed in the SEM analysis, which indicated that autonomy had a direct effect on IPV suggesting that women who are in relationships that allow them to make decisions along with their partners possibly experience less IPV. In addition BGE, which was hypothesized to play a mediating role showed a significant direct association with IPV,

suggesting that women who are aware of their rights may experience less IPV by choosing partners who do not espouse hegemonic masculinities or strong patriarchal beliefs. Our findings suggest that it would be important to incorporate decision-making skills and human rights awareness in future community-based sexual health and reproductive rights interventions.

Keywords

intimate partner violence, self-determination, gender equality beliefs, young women

Introduction

Researchers and policy makers from around the globe have made a concerted effort into getting intimate partner violence (IPV) recognized as a serious public health problem that has devastating outcomes for many societies (Grose & Grabe, 2014; Russell et al., 2014; Stöckl, Devries, & Watts, 2015; van Niekerk & Boonzaier, 2016). South Africa is one of the highest ranking countries in IPV prevalence, where 20% to 50% of ever-partnered adult women have reported ever experiencing physical, sexual, or emotional violence (Abrahams et al., 2014; Devries et al., 2013; Shai & Sikweyiya, 2015). In the last two decades, South African researchers, health practitioners, and activists have initiated and conducted work to mobilize communities and to develop solutions for addressing IPV (Abrahams et al., 2014; Jewkes, 2002; Jewkes, Dunkle, Nduna, & Shai, 2010; Kim et al., 2007; Meintjes, 2003; Seedat, Van Niekerk, Jewkes, Suffla, & Ratele, 2009). There have been some positive effects, for example, the government previously labeled IPV as a private matter not needing any specific interventions; now, IPV is recognized as a punishable criminal offence (Domestic Violence Act 116, 1998; Meintjes, 2003; Mogale, Burns, & Richter, 2012; Seedat et al., 2009). However, the surface has barely been scratched, as South Africa still remains one of the highest ranking countries in IPV prevalence.

This article investigates correlates of IPV among young South African rural women. Earlier research focused on investigating personal and interpersonal factors associated with IPV, where it was shown that women who have poor education and low or no income tend to be more vulnerable to violent sexual relationships (Abrahams et al., 2014; Dunkle et al., 2004; Jewkes, 2002). In addition, alcohol or substance use by women or their partners predisposes women to IPV (Abrahams et al., 2014; Abramsky et al., 2011; Dunkle et al., 2004; Gass, Stein, Williams, & Seedat, 2011).

The research into personal and interpersonal risk factors of IPV has been important and useful in helping identify subgroups that are susceptible to violence.

However, these factors do not fully explain the underlying factors that drive, maintain, or increase IPV. To fully understand the drivers, we have to first understand the context within which violence occurs. Theories at different ecological levels are good instruments that can help us achieve this goal by enabling us to consider the interactions of personal, family, community, and social factors and how these influence interpersonal relationships, and in turn how that influence contributes to victimization and perpetration of violence (Ali & Naylor, 2013; Bell & Naugle, 2008; Cavanaugh, Hansen, & Sullivan, 2010; Koenig, Ahmed, Hossain, & Mozumder, 2003).

In this study, we used SDT with the aim of identifying psychosocial factors that contribute to women's exposure to or protection against IPV. SDT hypothesizes that human beings have three psychological needs, namely, *competence*, *autonomy*, and *relatedness*, which have to be met for individuals to have good health outcomes. When the three SDT needs are met, individuals gain psychological strength to start and maintain healthier behavior (Silva, Marques, & Teixeira, 2014). The *autonomy* need is described as a fundamental human need; it provides an environment that enables freedom and agency in life situations. This means that decision making in sexual relationships is experienced or understood as an exercise where both partners willingly participate. This is mainly determined by whether or not both partners cultivate autonomy. The autonomy need being described here is distinct from the concepts of individualism, independence, and separateness. Also, autonomy should not be understood as being the opposite of dependence; it should rather be understood as being the opposite of heteronomy—a concept where an individual is forced to adopt decisions, in this case by a sexual partner, despite strongly holding different views or interests (Chirkov, Ryan, Kim, & Kaplan, 2003). *Competence* involves feeling effective in ongoing interactions with one's external environment; it also forms the foundation for self-esteem and self-confidence (Ng et al., 2012; Sheldon, Ryan, & Reis, 1996). The *competence* need is also linked to one's control of motivations, where an individual is able to plan and strategize on different routes needed to progress toward a goal (Ng et al., 2012; Patrick, Knee, Canevello, & Lonsbary, 2007). *Relatedness* can be defined as feeling connected to a partner, feeling secure, having a sense of belonging with others, in a social environment (Patrick et al., 2007; Weinstein & Ryan, 2011). The three psychological needs in life situations where well-being is promoted have been shown to enable freedom and agency. Moreover, these needs being met means that decisions and

beliefs are internalized and therefore will be sustained in the long term (Patrick et al., 2007; Weinstein & Ryan, 2011). Therefore, it is important to investigate whether women who feel autonomous, competent, or efficacious in enacting safe sexual behaviors and who feel connected to their partners and their social networks are protected against IPV.

In addition, gender-power ideologies at interpersonal and community levels were also considered because research shows that gender relations play an important role in the exposure or perpetration of IPV (Gibbs, Sikweyiya, & Jewkes, 2014; Morrell, Jewkes, & Lindegger, 2012; Pettifor, MacPhail, Anderson, & Maman, 2012; Shefer et al., 2008). IPV thrives in societies that are organized along patriarchal lines, and South Africa is an example of such a society. Even though the constitution recognizes equal and inalienable human rights for males and females, as well as the representation of women in politics and in education, the recognition of these rights is yet to translate to social spaces (Bill of rights, South Africa; Section 9(4), 1996). Women continue to be in social positions that are insecure as is evidenced by the lack of socio-economic resources and not having a voice in many local and traditional matters, especially in rural communities (Albertyn, 2011; Walker & Barton, 2013). In environments where experiences of manhood and womanhood are dictated by oppressive and very conservative traditions, power shifts to men and norms that valorize hegemonic masculinities are promoted. The promotion of hegemonic masculinities is characterized by placing value on physical strength, aggression, control of female partner, expression of virility, male entitlement, and gender inequitable attitudes (Albertyn, 2011; Pettifor et al., 2012; Walker & Barton, 2013). Women, however, are expected to be demure and acquiescing especially in sexual relationships (Albertyn, 2011; Pettifor et al., 2012; Walker & Barton, 2013). Also such societies are often restrictive and punitive on women to such an extent that when women are victims of interpersonal violence in sexual relationships, they often do not challenge their situation nor report it. Instead, they live in fear, or they just try to cope because IPV is often still branded a private matter in South African communities (Shai & Sikweyiya, 2015). In this study, we wanted to understand whether rural women internalize negative or positive gender ideologies (power and violence beliefs), and if so, what associations does that have with women's IPV victimization or absence thereof.

We hypothesized that the three psychological needs constructs—autonomy, competence, and relatedness—would be associated with young women's victimization to IPV and that gender-power constructs would mediate the association of the three needs with IPV. Gender-power constructs were hypothesized to play a mediating role because they are understood to represent the underlying socio-cultural mechanisms that explain how an individual's feelings of

autonomy, competence, and relatedness influence whether or not they get exposed to IPV. This means that women's beliefs about gender-power issues depend on how empowered they are, and these beliefs in turn are important in the choice of partners and thus the chances of being exposed to IPV.

Method

Study Setting and Sampling

This article reports on a component of baseline data that were collected as part of a randomized-controlled trial (Mpondo, Ruiter, van den Borne, Reddy, 2015). From September 2012 to March 2013, participants were recruited from the OR Tambo and Amathole district municipalities of the Eastern Cape Province, South Africa; both districts lie along the Eastern seaboard of the Indian Ocean. Women were recruited through an extension network of the Eastern Cape Royal Chiefs' [Imbumba Yoomama Bakomkhulu/IYA] a local tribal authority and development organization. IYA members recruited local women for the study through the word of mouth in community structures. Community research assistants (CRAs) then contacted those women via telephone for screening and to set baseline assessment interview appointments. Participants were eligible if they were between 18 to 35 years of age, had low levels of education (below South African Senior certificate), were Xhosa speaking, were unemployed at entry of study, and were not pregnant. The selection criteria were established from the needs analysis conducted prior to baseline data collection, where the profile of women exposed to adverse physical (particularly sexual risk) and psychological health was developed. A total of 270 eligible women were sampled, and of those, 238 completed the questionnaire. The remainder did not meet the inclusion criteria due to one of the following reasons: possible relocation plans, reporting of mental illness, not attending appointments for the baseline assessment, and refusing participation.

Procedure

Data were collected by six trained isiXhosa-speaking, female CRAs. The CRAs were familiarized with the objectives of the study, trained on how to recruit participants, obtained informed consent, and administered the questionnaire. All questionnaires were administered in isiXhosa through face-to-face interviews. The assessments were carried out at the local tribal authority homesteads because these were centrally located and accessible to all participants. Prior to conducting interviews, participants were verbally informed about the

content of the study, procedures, and confidentiality. At the end of the information session, written consent was obtained from each participant. Ethical approval was obtained from the Walter Sisulu University Bio-Ethics Committee.

Measures and Scale Construction

The questionnaire measures were selected to assess young women's IPV victimization preceding the baseline interview. The primary questionnaire was developed in English and then translated to isiXhosa for comprehension, cultural applicability, and language appropriateness, and subsequently back translated to English to check for accuracy, and finally pretested on Xhosa-speaking women.

Socio-Demographic Variables

Socio-demographic variables included age, highest grade passed (1 = *no schooling to primary schooling*, 2 = *secondary schooling*, and 3 = *post matric*), and marital status (dichotomized to 1 = *married* and 2 = *not married*). Employment status of the participant and their partner (categorized as unemployed, disabled, social grant, employed less than 5 days or employed more than 5 days) as well as household income in South African Rand were assessed (see also Table 1).

Sexual Behavior

The sexual behavior question assessed whether a person had a sexual primary partner (0 = *no*, 1 = *yes*) and a secondary/casual partner (0 = *no*, 1 = *yes*). One open-ended question asked about the number of men a participant had sex with in the past 3 months. Another open-ended question asked "How old is the person you last had sex with?"

Measures

For the measures below, confirmatory factor analysis (CFA) was conducted using SPSS Version 22 (SPSS Inc., Chicago, IL) as pre-analysis and to check whether items indeed grouped together as would be expected. Scree plots and principal-axis factor analysis and direct oblimin rotations were used for extracting factors. Items with factor loadings of .40 or higher were grouped and subjected to reliability analysis. Groups of items with a Cronbach's alpha score of .60 or higher were averaged into a single construct and labeled to reflect the underlying variable that was measured. All measures were based on

Table 1. Socio-Demographic Profile of Sampled Women Living in Rural Communities in the Eastern Cape (N = 238).

Variables	Frequency (Cumulative %)	%
Education level		
No formal schooling	1 (0.4)	0.5
Primary school	8 (3.4)	3.7
Secondary school	164 (68.9)	76.3

Above 10,000	12 (3.7)	3.8

Likert-type items, unless otherwise indicated. Items and variables were recoded such that higher scores reflect a stronger presence of the pertinent variable.

IPV Measures

The number of incidences of IPV was assessed with three separate questions with yes/no answer options: “In the past 3-months have you been . . .”(a)

sexually abused by your partner, (b) physically abused by your sexual partner, and (c) emotionally abused by your sexual partner.

IPV was assessed with a five-item scale that focused on physical and verbal abuse, the response options were from 0 = *never* to 3 = *always* (i.e., “Does your partner ever yell or curse at you?” “Does your partner ever threaten to leave you?” “Does your partner ever threaten to hit you?” “Has your partner ever hit you?” “Did your partner ever leave you?”; $\alpha = .80$). *IPV* served as the main outcome measure for this study.

Beliefs about IPV were assessed with a four-item scale with response options from 1 = *strongly agree* to 5 = *strongly disagree*. The scale was assessed with the following questions: “There are times when a woman deserves to be beaten,” “If a woman insults her man, he should defend his reputation with force,” “A man using violence against his wife is a private matter that should be discussed only by the couple,” and “A woman should tolerate violence to keep her family together” ($\alpha = .60$). A higher score reflected more negative beliefs toward *IPV*. *IPV* and *beliefs about IPV* were both taken from the Compendium of Gender Scales (Nanda, 2011).

Three SDT Psychological Needs

We operationalized the three SDT psychological needs (*autonomy*, *competence*, and *relatedness*) by using measures that we theoretically and conceptually linked to each of the needs, respectively. Autonomy was assessed with a measure of *attitude toward decision making*, competence with a measure of *self-efficacy to practice safe sex*, and relatedness was measured with an *Interpersonal Support* sub-scale. Attitude toward decision making was measured with a six-item scale with response options from 1 = *strongly disagree* to 5 = *strongly agree* obtained from the Compendium of Gender Scales (Nanda, 2011). Example items are “No one should have more power than the other in a relationship” and “My partner and I sit down and discuss important matters” ($\alpha = .70$). A higher score reflected more positive attitudes toward equal decision making in a sexual relationship.

Self-efficacy to practice safe sex was measured with a six-item scale with answering options from 1 = *strongly agree* to 4 = *strongly disagree* (Brafford & Beck, 1991) with items such as “I am certain I know how to use a condom correctly” and “I am confident that I can have safe sex and satisfy my partner” ($\alpha = .80$). Scores were coded such that higher scores reflect more self-efficacy to practice safe sex.

Interpersonal support was measured with a 28-item scale with scoring options ranging from 0 = *definitely false* to 3 = *definitely true*; Brookings & Bolton, 1988). Factor analysis showed a two-factor solution, *Presence of*

Support (e.g., “If I were sick I could easily find someone to help me with my daily activities” with a total of 11 items, three items were dropped after reliability analysis; $\alpha = .74$) and *Lack of Support* (e.g., “If a family crises arose, it would be difficult to find someone who could give me good advice about how to handle it” with a total of 14 items; $\alpha = .72$). In our analysis, *Presence of Support* was used because it best captured the concept of relatedness with higher scores reflecting more presence of support.

Beliefs About Gender Equality (BGE)

BGE were measured with a four-item scale with response options from 1 = *strongly agree* to 5 = *strongly disagree*: “If both of us are working, the husband should do the same amount of chores as the wife,” “I believe a woman’s place is in the home,” “In our family, as a wife I should not work outside unless it is a financial necessity,” and “The husband should have the final word in most of the important decisions in our family.” After re-coding, a higher score reflected having more positive *beliefs toward gender equality* ($\alpha = .60$).

Model Development and Analysis

A step-wise structural equation modeling (SEM) was conducted using MPlus Version 7.11 (Muthén & Muthén, 2013) to assess the fitness of the proposed conceptual model. First, CFA was conducted with the aim of testing or confirming SPSS results (Byrne & Stewart, 2006). All measures were confirmed to be one-factor constructs except for the presence of support (relatedness) and self-efficacy to practice safe sex (competence), which were shown to each have two factors. For presence of support, the factor with four items was used, and for self-efficacy to use a condom, a factor with three-items was used for further analysis. The other factors for both measures were dropped to improve model fit. In the next step, a measurement model was fitted with all latent variables tested as second-order factors. A maximum likelihood estimator (MLR) was used to account for the fact that there were some missing data points; about 1.3% to 4.4% data points were missing for the respective measures used in this analysis. The MLR estimator uses standard errors and a chi-square test statistic that is robust to non-normality (Yuan–Bentley χ^2).

Subsequently, a full structural model based on the theoretical conceptual model was specified. The sample ($N = 238$) was used for both the measurement and structural models, and even though it was relatively small, it allowed for a well-specified model to be tested (Jackson, 2001). The following statistics were used to assess an adequate structural model fit, such as the comparative fit index (CFI; Bentler, 1990), the root mean square root error of

approximation (RMSEA; Steiger, 1990), and a standardized root mean square residual (SRMR). A CFI that is ≥ 0.90 or ≥ 0.95 , RMSEA must be ≤ 0.08 or ≤ 0.05 , and SRMR should be ≤ 0.08 (Hu & Bentler, 1999). Furthermore, indirect effects from the structural model were tested using bootstrapped standard errors ($n = 5,000$) to construct 95% confidence intervals.

Results

Demographic Profile of Participants

A total of 238 women were interviewed at baseline of the study. The mean age of those women was 25.9 years ($SD = 4.37$ years) with the youngest being 18 years and the oldest being 35 years. All participants were Xhosa speaking. Other socio-demographic characteristics are included in Table 1.

Sexual Behaviors and Intimate Violence Exposure

About 66% of the participants in the study reported having a partner (main or casual). The majority (87.4%) of the participants reported having had sex with one partner in the last 3 months, while 9.7% reported having had more than one sexual partner in the same 3-month period. A minority of the participants (39.4%) reported using condoms at last sex, and 11.2% reported ever having had a sexually transmitted infection (STI). The mean age of the participants' sexual partners was 30 years ($SD = 6.00$ years) with the youngest partner being 18 years and the oldest being 49 years. About 12.7% of the young women reported having a sexual partner who was 36 years and older. In terms of victimization, about 36% of participants had been verbally abused by their partner. About a quarter (26%) of the participants were physically abused (beaten or hit) by their sexual partners.

Bivariate Correlations

Inter-item correlations are presented in Table 2. In terms of effect sizes, weak associations are correlations with Pearson r between .10 and .23; a correlation between .24 and .36 shows an association of moderate strength, and a correlation of $r \geq .37$ indicates a strong association (Cohen, 1988). The bivariate correlation analysis showed that BGE, autonomy, and relatedness were negatively associated with IPV representing weak associations. Beliefs about partner violence (BPV) and competence were not significantly associated with IPV. In addition, BPV was positively associated with competence representing a moderate association. Autonomy and relatedness were negatively

Table 2. Correlation Matrix of the Latent Variables for the Structural Equation Model.

Measure	1	2	3	4	5	6
1. IPV	—					
2. BPV	-.07	—				
3. BGE	-.19**	.05	—			
4. Autonomy	-.21**	.08	-.16**	—		
5. Com_S	-.07	.27**	.18**	.36**	—	
6. Relatedness	-.19**	-.03	-.29**	.25**	.14*	—

Note. IPV = intimate partner violence; BPV = beliefs about partner violence; BGE = beliefs about gender equality; autonomy = operationalized with attitudes toward decision making; Com_S = competence operationalized with self-efficacy to practice safe sex; relatedness = operationalized with presence of support.

* $p < .05$. ** $p < .01$.

associated with BGE representing weak to medium associations. Competence and relatedness showed moderate positive associations with autonomy.

Measurement Model

The results of the CFA analysis and the hypothesized measurement model with all factors structures are presented in Table 3. The hypothesized conceptual measurement model fit was just adequate ($\chi^2 = 379.037$; $df = 307$, $p < .001$; CFI = 0.947; Tucker–Lewis index [TLI] = 0.929; RMSEA = 0.038; SRMR = 0.05, $p < .05$). To improve the fit, single items from BGE and BPV were dropped, as they did not fit well with their constructs (low factor loadings; Brown, 2015). The fit for the complete measurement model improved ($\chi^2 = 307.194$; $df = 237$, $p < .001$; CFI = 0.939; TLI = 0.929; RMSEA = 0.035; SRMR = 0.05, $p < .05$).

Structural Model

Figure 1 depicts the results of the hypothesized structural model, which highlights the relations of the latent variables. The significant paths are indicated with bold arrows, the corresponding factor loadings are also indicated for all the paths. The fit of the final structural model was good ($\chi^2 = 313.980$; $df = 239$, $p < .001$; CFI = 0.935; TLI = 0.925; RMSEA = 0.036; SRMR = 0.06, $p < .05$). In terms of the direct effects, the autonomy to IPV path was significant and negative (standardized structural coefficient = $-.24$; $p = .01$) suggesting that women who felt autonomous in their sexual relationships may have

Table 3. Model Fit Statistics for the Confirmatory Factor Analysis.

Measure	Model	Observed	YB- χ^2	df	CFI	TLI	RMSEA	SRMR
Com_S	Competence	3	0.000	0	1.000	1.000	0.00	0.00
Presence of support	Relatedness	4	3.155	2	0.980	0.941	0.05	0.03
Attitudes toward decision making	Autonomy	6	19.076	9	0.940	0.901	0.07	0.05
Intimate partner violence	IPV	5	4.978	5	1.000	1.000	0.00	0.02
Beliefs about partner violence	BPV	3	0.000	0	1.000	1.000	0.00	0.00
Beliefs about gender equality	BGE	3	0.000	0	1.000	1.000	0.00	0.00
All	Complete model	24	307.194	237	0.939	0.929	0.035	0.05

Note. Observed = variable count; YB- χ^2 = Yuan-Bentler rescaled; df = degrees of freedom; CFI = comparative fit index; TLI = Tucker-Lewis index; RMSEA = root mean squared error of approximation; SRMR = standardized root mean squared residual.

experienced less IPV victimization. The relatedness path to IPV showed a tendency toward significance (standardized structural coefficient = $-.19$; $p = .10$), whereas competence showed no significant association with the outcome variable (IPV). The results of the hypothesized indirect paths were analyzed according to the empirical conditions of mediation (Baron & Kenny, 1986). A significant negative direct path from BGE to IPV (standardized structural coefficient = $-.26$; $p = .02$) was observed, the competence to BGE path was also significant with a positive association (standardized structural coefficient = $.28$; $p = .02$). The results described above suggest that BGE is a full mediator of the competence and IPV path. The hypothesized indirect path of autonomy to IPV through BGE only showed a tendency toward significance (standardized structural coefficient = $-.21$; $p = .08$) while the direct path from autonomy to IPV was significant therefore suggesting that BGE was not a mediator between autonomy and IPV. The relatedness (indirect) path through BGE also only showed a tendency toward significance (standardized structural coefficient = $-.21$; $p = .10$) suggesting that there was no mediation through this path either. The observed indirect path of competence to IPV was subjected to MPlus test for mediation to verify whether indeed there was mediation; however, the test yielded no significant statistical results ($z = -1.113$; $p = .30$). No significance was observed for the hypothesized indirect path between competence, BPV, and IPV thus suggesting that even

Figure 1. Structural latent variable model of operationalized three-SDT needs as predictors of IPV (standardized coefficients). Note. Bold arrows denote statistically significant paths as well as those that show tendency toward significance. Fit indices: $\chi^2 = 313.980$; $df = 239$, $p < .01$; CFI = 0.935; TLI = 0.925; RMSEA = 0.036; SRMR = 0.06, $p < .00$. SDT = self-determination theory; Autonomy = operationalized with attitudes toward decision making; BPFV = beliefs about partner violence; Com_S = Competence operationalized with self-efficacy to practice safe sex; IPV = intimate partner violence; Relatedness = operationalized with presence of support; BGE = beliefs about gender equality; CFI = comparative fit index; TLI = Tucker-Lewis index; RMSEA = root mean squared error of approximation; SRMR = standardized root mean squared residual. * $p < .10$. ** $p < .05$. *** $p < .01$.

though the path from competence to BPV was significant (standardized structural coefficient = .28; $p = .00$), BPV in turn did not relate to IPV.

Discussion

More than a quarter of young women (18-35 years) in our study reported having experienced verbal or physical violence by their sexual partners in their most recent relationships. This finding highlights the persisting problem in sexual relationships among South African young women (Devries et al., 2013; Shai & Sikweyiya, 2015). The reported verbal or physical violence, which may even have been underreported here, and the reports of inconsistent condom use (only 40% of women said that they used condoms at last sex) indicate that women continue to be exposed to adverse health conditions. Especially because previous studies have shown that violence and lack of condom use are strongly linked to the risk of HIV infection (Decker et al., 2014; Karamagi, Tumwine, Tylleskar, & Heggenhougen, 2006).

Bivariate analyses showed that autonomy and relatedness had significant associations with IPV. Of these two latent variables, autonomy was shown to have a significant direct association with IPV in the SEM as well, whereas relatedness was not shown to have a direct effect on the outcome variable. Autonomy being negatively associated with IPV may mean that women who feel a sense of agency or who feel included or consulted by their partners in decision making within sexual relationships are less likely to be exposed to verbal physical and sexual violence possibly because joint decision making acknowledges each partner's values and cultivates trust in a sexual relationship, and as such, the male partner will be less likely to assert himself through violence (Minnis et al., 2015; Ogland, Xu, Bartkowski, & Ogland, 2014).

BGE did not mediate the effect of autonomy on IPV. But the fact that it has a significant negative direct association with IPV is important, suggesting that women who hold gender equality beliefs may involve themselves less in oppressive relationships and thus get exposed less to violence (DePadilla, Windle, Wingood, Cooper, & DiClemente, 2011; Wingood et al., 2013). They may choose partners who do not espouse hegemonic masculinities as those partners who do may be perceived as violent. Furthermore, the association also highlights the importance of including human rights in interventions, especially how these rights can be practiced or applied in personal situations. These interventions should help women understand that relationships that recognize equality of partners are healthier than those that do not, and it would be important to promote autonomy and competence feelings for healthier (sexual) relationships.

The indirect path of competence to IPV via BGE needs further investigation, as it was shown to be significant in the SEM but not proven to be so in the mediation analysis possibly due to power issues as our sample was relatively small. Furthermore, competence being positively associated with BGE suggests that women who are efficacious in practicing safe sex or suggesting condom use also have an ability to choose healthier relationships and therefore may experience less violence (DePadilla et al., 2011; Wingood et al., 2013). Even though in the structural model BGE was also not shown to mediate the path between autonomy and IPV, it is important to understand the relationship between autonomy and BGE as the concept of equality is proximal to having the need for autonomy met. Further research may help us better understand the association between these concepts.

Also further research is needed to better understand the significant negative bivariate association between BGE and relatedness that approached significance in the structural model. Past research shows that in cases where social support was not present, women were shown to be more likely to suffer from mental ill health (stress and depression), and in worst cases, psychiatric morbidity (Coker et al., 2002). Beyond sharing challenges about sexual relationships, social networks are used for practical purposes such as poverty alleviation especially because unemployment is so rife in rural communities. It would be interesting to understand what role relatedness plays in preventing women from being involved in violent relationships, especially in a patriarchal context such as the one where our study was conducted.

We conclude that this study supports the SDT theory by showing that autonomy (direct effect) and competence (indirectly through BGE) measures are associated with less exposure to verbal and physical IPV. This means that teaching women to pursue relationships that will promote and cultivate the fulfillment of the three SDT needs may prevent them from being vulnerable and may also enable them to live healthier lives.

Furthermore, the sample size was relatively small, and women were recruited through IYA; therefore, our sample may not be representative of all rural, poor women in the Eastern Cape or South Africa. Also, our measures relied on self-report on sensitive information about sexually related issues, and participants may have provided responses that are perceived to be socially desirable. However, efforts were made by our research team to encourage honest responses from the participants. Finally, we designed a cross-sectional study, which may not have fully captured the hypothesized effects of the three needs on IPV. Therefore, a longitudinal study may be a better design for capturing these relationships. Aside from the limitations of our investigation, this work highlights that it is important to identify new psychosocial determinants of IPV because it is a complex and persisting problem. This way,

identified correlates can help in the formulation of new change objectives for interventions to reduce women's exposure to IPV.

Authors' Note

Stefan Gruijters (Maastricht University) was consulted for the statistical analysis conducted here.

Declaration of Conflicting Interests

The author(s) declared no potential conflicts of interest with respect to the research, authorship, and/or publication of this article.

Funding

The author(s) disclosed receipt of the following financial support for the research, authorship, and/or publication of this article: The Ford Foundation (Grant 11050509-0) funded the development and implementation of this study. The manuscript preparation (toward a PhD dissertation) activities from which this study emanates was funded by the South African Medical Research Council-National Health Scholars Program from funds provided by the Public Enhancement fund. Additional funds were also received from Stichting Studiefonds voor Zuid-Afrikaanse Studenten (SSF, The Netherlands).

Author Biographies

Feziwe Mpondo is a PhD candidate at the Department of Work and Social Psychology, Faculty of Psychology and Neuroscience, Maastricht University in the Netherlands. The focus of her PhD work is to understand the determinants of poor (physical, mental, and reproductive) health outcomes for women who live in rural communities of South Africa. She was trained in the Biotechnology and Biomedical sciences for her Bachelor's and Master's degrees; because she had a keen interest in health promotion and public health, she went on to work as a Researcher for the South African Medical Research Council before pursuing her PhD.

Robert A. C. Ruiter is a professor of Applied Psychology and the head of the Department of Work and Social Psychology in the Faculty of Psychology and

Neuroscience at Maastricht University. His core research is on the effectiveness of persuasive messages, with a keen interest in the process of attention, information processing, and behavior change. He is also involved in studies that are based in the domains of Cognitive Psychology and Neuroscience, respectively. He has a number of publications that are based on the above-mentioned work. He is also a senior lecturer and course coordinator at Maastricht University.

Bart van den Borne has been affiliated with Maastricht University since 1992, first as an associate professor and later as a professor of patient education. He has also served as a vice-dean of the Faculty of Health Sciences for several years. He is currently the scientific director of the International Public Health Master at the Faculty of Health, Medicine, and Life Sciences, Maastricht University. He was the first professor of patient education in the Netherlands. He is also committed to sharing knowledge about health promotion in developing countries; this, he does through training PhD candidates.

Priscilla S. Reddy is the deputy executive director of the Population Health, Health Systems, and Innovations Research Program at the Human Sciences Research Council. She is a former director of the Health Promotion and Development Unit of the South African Medical Research Council. She founded this unit to establish health promotion as a new discipline in South Africa. She has also been a visiting professor at the Nelson Mandela School of Medicine, KwaZulu Natal; a visiting associate professor at the Rollins School of Public Health, Emory University; and various other Health Institutions in the United States.
